presents a detailed study of the major design components that constitute a top down decision tree induction algorithm including aspects such as split criteria stopping criteria pruning and the approaches for dealing with missing values whereas the strategy still employed nowadays is to use a generic decision tree induction algorithm regardless of the data the authors argue on the benefits that a bias fitting strategy could bring to decision tree induction in which the ultimate goal is the automatic generation of a decision tree induction algorithm tailored to the application domain of interest for such they discuss how one can effectively discover the most suitable set of components of decision tree induction algorithms to deal with a wide variety of applications through the paradigm of evolutionary computation following the emergence of a novel field called hyper heuristics
